Direct multiple shooting matlab

direct multiple shooting matlab is a powerful numerical method widely used in solving complex

optimal control problems, especially those involving dynamic systems with constraints. This technique offers enhanced stability and accuracy over traditional methods, making it a popular choice among engineers and researchers working in fields such as robotics, aerospace, automotive control, and process engineering. MATLAB, renowned for its robust computational capabilities and extensive toolboxes, provides an ideal environment to implement the direct multiple shooting method efficiently.

In this comprehensive guide, we will explore the concept of direct multiple shooting in MATLAB, its mathematical foundations, implementation steps, advantages, and practical applications. Whether you are a beginner looking to understand the basics or an experienced practitioner seeking advanced insights, this article aims to serve as a detailed resource.

Understanding Direct Multiple Shooting Method

What is the Direct Multiple Shooting Method?

The direct multiple shooting method is a numerical technique used to solve boundary value problems (BVPs) and optimal control problems (OCPs). It divides the original problem into smaller subproblems, called shooting intervals, which are easier to handle computationally. The solutions of these subproblems are then stitched together to form a global solution that satisfies the overall system dynamics and boundary conditions.

This approach extends the classical single shooting method by introducing multiple shooting points, which improve convergence properties, especially for stiff or highly nonlinear systems.

Comparison with Other Numerical Methods

Method	Description	Advantages	Disadvantages
-----	-----	-----	-----
Single Shooting	Integrates the system from initial condition to final time directly	Simpler implementation	Sensitive to initial guesses, poor for stiff systems
Collocation	Uses polynomial approximations and collocation points	High accuracy, good for complex problems	More complex to implement
Multiple Shooting	Divides the problem into segments, solves locally, enforces continuity	Better convergence, handles large problems	Slightly more complex setup

Mathematical Foundations of Direct Multiple Shooting

Problem Formulation

Consider a continuous-time optimal control problem:

$$\begin{aligned} & \min_{u(t)} \quad J = \phi(x(t_f)) + \int_{t_0}^{t_f} L(x(t), u(t), t) dt \\ & \text{subject to} \quad \dot{x}(t) = f(x(t), u(t), t), \quad t \in [t_0, t_f] \\ & \quad \quad \quad x(t_0) = x_0 \\ & \quad \quad \quad \text{path and boundary constraints} \end{aligned}$$

Where:

- $x(t)$ is the state vector
- $u(t)$ is the control vector
- f describes the system dynamics
- J is the cost functional

Discretization via Multiple Shooting

The interval $[t_0, t_f]$ is divided into N subintervals with points $t_0, t_1, \dots, t_N = t_f$. The main idea is to:

- Guess the initial states x_k at each shooting point t_k .
- Integrate the system dynamics from t_k to t_{k+1} using a numerical integrator (e.g., Runge-Kutta).
- Enforce the continuity constraints:

$$x_{k+1} = \Phi_k(x_k, u_k) \quad \text{for } k=0,1,\dots,N-1$$

\]

where Φ_k is the state transition function obtained from numerical integration.

- Formulate an optimization problem to find the control inputs u_k and states x_k that minimize the cost while satisfying the dynamics and boundary conditions.

Implementing Direct Multiple Shooting in MATLAB

Implementing the direct multiple shooting method involves several steps:

Step 1: Define the System Dynamics

Create a function that computes the derivatives of the states:

```
``matlab

function dx = system_dynamics(t, x, u)

% Example: Double integrator

dx = zeros(2,1);

dx(1) = x(2);

dx(2) = u;

end

``
```

Step 2: Discretize the Time Horizon

Choose the total time span and number of shooting intervals:

```
``matlab

t0 = 0;
```

```
tf = 10;
```

```
N = 20; % Number of shooting intervals
```

```
t_grid = linspace(t0, tf, N+1);
```

```
...
```

Step 3: Initialize Variables

Set initial guesses for the states and controls at each shooting point:

```
```matlab
```

```
x_guess = repmat([0;0], 1, N+1); % Initial guess for states
```

```
u_guess = zeros(1, N); % Control inputs
```

```
...
```

### Step 4: Formulate the Optimization Problem

Use MATLAB's optimization toolbox (e.g., `fmincon`) to minimize the cost function, which includes the sum of quadratic control efforts and terminal cost, subject to the dynamics constraints.

Define the cost function:

```
```matlab
```

```
function J = cost_function(U, x_guess, t_grid)
```

```
% U contains control inputs for all intervals
```

```
% Implement cost computation based on U and states
```

```
end
```

```
...
```

And the nonlinear constraints:

```
```matlab

function [c, ceq] = constraints(U, x_guess, t_grid)

% Integrate dynamics for each interval

% Enforce continuity constraints

end

```
```

Step 5: Numerical Integration within Constraints

Implement numerical integration (e.g., `ode45`) to propagate states between shooting points:

```
```matlab

for k = 1:N

 u_k = U(k);

 [~, x_traj] = ode45(@(t, x) system_dynamics(t, x, u_k), [t_grid(k), t_grid(k+1)], x_guess(:,k));

 x_end = x_traj(end,:);

% Store x_end and enforce continuity

end

```
```

Step 6: Solve the Optimization Problem

Use `fmincon`:

```
```matlab

options = optimoptions('fmincon', 'Display', 'iter', 'Algorithm', 'sqp');

U0 = zeros(1, N); % Initial guess
```

```
[U_opt, fval] = fmincon(@(U) cost_function(U, x_guess, t_grid), U0, [], [], [], [], [], @(U)
constraints(U, x_guess, t_grid), options);
```

```
...
```

Direct Multiple Shooting in MATLAB: A Comprehensive Guide for Optimal Control and Dynamic Systems

### Introduction

In the realm of numerical optimal control and dynamic system simulation, the direct multiple shooting method has gained significant prominence due to its robustness, flexibility, and efficiency. MATLAB, with its powerful computational environment and extensive toolboxes, provides an ideal platform for implementing this method. Whether you're tackling complex trajectory optimization problems, robotics motion planning, or aerospace vehicle control, understanding and leveraging direct multiple

shooting in MATLAB can dramatically enhance your solution quality and computational performance.

### What is Direct Multiple Shooting?

Direct multiple shooting is a numerical technique used to solve boundary value problems and optimal control problems. It is an extension and refinement of the classical shooting method, designed to improve convergence properties, especially for nonlinear and high-dimensional systems.

Key features include:

- Dividing the entire time horizon into multiple sub-intervals.
- Solving initial value problems (IVPs) on each sub-interval independently.
- Enforcing continuity constraints at sub-interval boundaries.
- Formulating the problem as a large-scale nonlinear programming (NLP) problem.

This approach combines the advantages of classical shooting methods with collocation techniques, providing enhanced stability and scalability.

### Why Use Direct Multiple Shooting?

Compared to single shooting, multiple shooting offers several benefits:

- Improved convergence: By segmenting the problem, the method avoids the sensitivity to initial guesses that plagues single shooting.
- Parallelization: Sub-problems on each interval can be solved independently, enabling parallel computation.
- Handling constraints: It facilitates the incorporation of path constraints more naturally.
- Flexibility: Suitable for problems with discontinuities, switching dynamics, or complex boundary conditions.

In MATLAB, these advantages translate into more reliable and efficient solutions, especially with the help of toolboxes like CasADi, ACADO Toolkit, or custom implementations.

### Mathematical Foundations of Direct Multiple Shooting

#### Problem Formulation

Consider a general nonlinear optimal control problem:

$$\begin{aligned}
 & \min_{u(t), x(t)} J = \Phi(x(t_f)) + \int_{t_0}^{t_f} L(x(t), u(t), t) dt \\
 & \text{subject to} \\
 & \dot{x}(t) = f(x(t), u(t), t), \quad t \in [t_0, t_f], \\
 & x(t_0) = x_0, \\
 & \text{state and control constraints:} \quad c(x(t), u(t), t) \leq 0.
 \end{aligned}$$

In direct multiple shooting, the time horizon  $[t_0, t_f]$  is partitioned into  $(N)$  sub-intervals:

$$t_0 = t_1$$

On each interval  $[t_k, t_{k+1}]$ :

- Initial state variables:  $(x_k = x(t_k))$ ,
- Control variables:  $(u(t))$  (often parameterized),
- State trajectory:  $(x(t))$  obtained by solving the IVP:

$$\dot{x}(t) = f(x(t), u(t), t), \quad t \in [t_k, t_{k+1}].$$

The problem becomes:

---

$$\begin{aligned} & \min_{x_k, u(t)} J = \Phi(x_N) + \sum_{k=1}^N \int_{t_k}^{t_{k+1}} L(x(t), u(t), t) dt, \\ & \text{subject to} \\ & x_{k+1} = \text{integration of } f \text{ from } t_k \text{ to } t_{k+1} \text{ starting at } x_k, \\ & c(x(t), u(t), t) \leq 0, \quad \text{for all } t \in [t_k, t_{k+1}]. \end{aligned}$$

The continuity constraints enforce:

$$x_{k+1} = \text{flow}(x_k, u_k, t_k, t_{k+1}).$$

These are incorporated as equality constraints in the NLP.

## Implementation in MATLAB

Implementing direct multiple shooting in MATLAB involves several key steps:

- Problem Discretization and Parameterization
- Time grid creation: Decide on the number of sub-intervals  $(N)$  and generate the time points.
- Control parameterization: Choose whether controls are piecewise constant, linear, polynomial, or use other basis functions.

- Initial guesses: Provide initial guesses for states and controls to aid convergence.
- Forward Integration (Simulating Sub-intervals)
  - Use MATLAB's ODE solvers (`ode45`, `ode15s`, `ode113`, etc.) to integrate the dynamics on each sub-interval, starting from the current estimate of the initial state.
  - Store the resulting trajectories and final states.
- Formulating the NLP
  - Define decision variables: initial states  $\{x_k\}$ , control parameters over each interval.
  - Impose continuity constraints: the final state of one interval equals the initial state of the next.
  - Incorporate path constraints and bounds on states and controls.
- Solving the NLP
  - Use MATLAB's optimization toolbox (`fmincon`) or specialized solvers like CasADi, IPOPT, or KNITRO via interfaces.
  - Provide gradient and Jacobian information if possible for faster convergence.
- Post-processing and Validation
  - Extract optimal trajectories.
  - Plot states and controls over time.
  - Verify constraints and optimality.

## MATLAB Code Snippet for Basic Implementation

Here's a simplified illustrative snippet:

```
```matlab
```

```
% Define parameters
```

```
N = 10; % number of sub-intervals

t0 = 0; tf = 10;

time_points = linspace(t0, tf, N+1);

% Initial guesses

x0_guess = zeros(2,1);

u_guess = zeros(1, N);

% Decision variables vector: [x1, ..., xN+1, u1, ..., uN]

% For simplicity, assume fixed control over each interval

% Define the objective function

function J = objective(vars)

% Extract states and controls

x = reshape(vars(1:(N+1)*2), 2, []);

u = vars((N+1)*2+1:end);

J = 0;

for k=1:N

% Integrate dynamics in each interval

xk = x(:,k);

[~, x_traj] = ode45(@(t,x) dynamics(x, u(k)), [time_points(k), time_points(k+1)], xk);

x_end = x_traj(end,:);

% Continuity constraint will be enforced separately

% Accumulate cost
```

```
J = J + sum(L(x_traj, u(k)));

end

end

% Constraints: continuity

function [c, ceq] = constraints(vars)

ceq = [];

% Enforce  $x_{k+1} = \text{flow}(x_k, u_k)$ 

x = reshape(vars(1:(N+1)*2), 2, []);

u = vars((N+1)*2+1:end);

for k=1:N

    xk = x(:,k);

    [~, x_traj] = ode45(@(t,x) dynamics(x, u(k)), [time_points(k), time_points(k+1)], xk);

    x_end = x_traj(end,:);

    ceq = [ceq; x_end - x(:,k+1)];

end

c = [];

end

% Optimization call

% Define bounds, initial guess, etc.

% Call fmincon or other solvers

...
```

(Note: The above code is highly simplified and for illustrative purposes; practical implementation requires careful handling of variables, derivatives, and solver settings.)

Advanced Topics and Variations

Collocation vs. Shooting

While multiple shooting discretizes the control trajectory into segments, collocation methods approximate states and controls with basis functions, enforcing dynamics at collocation points. MATLAB implementations often combine these approaches, leading to direct collocation with multiple shooting.

Handling Discontinuities and Hybrid Systems

Multiple shooting is particularly adept at handling hybrid systems, where dynamics switch modes or involve discontinuities. The segmentation allows for resetting the states at switching points and maintaining stability.

Parallel Computing

MATLAB's Parallel Computing Toolbox enables parallelization of sub-interval integrations, significantly reducing computation times for large-scale problems.

Software Packages

- CasADi: Open-source framework supporting automatic differentiation, optimal control, and multiple shooting.
- ACADO Toolkit: C++ library with MATLAB interface for real-time optimal control.
- GPOPS-II: MATLAB software for collocation-based optimal control, which can incorporate multiple shooting strategies.

Practical Tips for MATLAB Implementation

- Good Initial Guesses: Improves convergence; consider solving simplified versions first.
- Gradient Computation: Use automatic differentiation tools or analytical derivatives to enhance solver performance.
- Constraint Handling: Be cautious with inequality constraints; enforce bounds explicitly.
- Solver Settings: Adjust tolerances, step sizes, and maximum iterations appropriately.
- Parallelization: Use ``parfor`` loops when integrating sub-intervals independently.
